Seismic Noise Under the Ground

1.1 Introduction

1.1.1 Site on the Ground Surface

1.1.2 Site under the Ground

1.1.3 KAGRA Site

1.2 Theory of Seismic Waves

1.2.1 Seismic Waves

1.2.2 Depth Dependence

1.2.3 ...

1.3 Seismic Noise

1.3.1 Problematic Seismic Noise

1.3.2 The Microseisms

1.3.3 The Earth Quakes

I have to explain how earth quake shake the KAGRA site and how serious for interferometer.

-
- Mechanism and frequency of earthquake?

1.3.4 The Earth Tide

- To explain accuracy of GIF in low frequency comparison with seismometers, This subsection describe about the measurement of the Earth Tide using GIF, which is consistent with the GOTIC model.

1.3.5 ...

1.4 Differential Motion Reduction on the Bedrock

1.4.1 Introduction

The seismic noise shakes both the common and the differential motion of the arm cavity. The common motion moves the center of mass of that, and the differential motion moves the arm length. These motions are the same each other, when two mirrors in the cavity moves with no correlation. However, If there is the coherence, the differential motion is less than common motion.

A ratio of the amplitudes of the differential motion over common motion on the ground is defined as Common and Differential Motion Ratio (CDMR). It is usefull value to know how the groung reduct the differential motion or increase the common motion in the arm cavity. This redcuton relax the controls of the arm cavity.

The coherence depends on both the arm length and the wave length of seismic waves, which is discussed in this section. For example, if the arm length is much smaller than the wave length, two mirrors in the cavity moves together. It means that the common motion is greater than the differential motion. Additionally, the wave length differs depending on the phase velocity of the seismic waves on the ground. Especially in KAGRA, the velocity is much higher than other sites because of the gneiss in the mine.

In fact, we need to consider about the common motion; because the arm length fluctuation is caused by not only the disturbance from the differential motion but also the coupling from the common motion. This coupling ratio is known as the Common Mode Rejection Ratio (CMRR). This is defined as the ratio of the powers of the differential-mode response over the common-mode response in a system.

In this section, CDMR is discussed in detail, while CMRR is not disscused.

1.4.2 Differential Motion Reduction

Motions of two mirrors in the arm cavity can be represented as the differential and the common motion. These motions are defined and calculated with the coherence between these two mirrors.

In folowing disscusion, the mirrors are fixed on the ground and these of CMRR is high enough to ignore the coupling from common motion of ground to differential motion of the mirrors.

Differential Motion and Common Motion

Figure 1.1: Displacements of two points, x_1, x_2 . Displacements of each location are represented as $u(x_1, t), u(x_2, t)$, in the case displacement field is given with $u(x, t)$, where x is location of the point and t is a time.

Displacement of both differential motion and common motion of two points shown in Figure 1.1 is defined as

$$u_{\text{diff}} \equiv \frac{u_1 - u_2}{\sqrt{2}}, \quad u_{\text{comm}} \equiv \frac{u_1 + u_2}{\sqrt{2}} \quad (1.1)$$

, where $u_1(x, t)$ and $u_2(x, t)$ are the displacement in each points.

Common and Differential Motion Ratio (CDMR)

Common and Differential Motion Ratio (CDMR) is defined as the powers of common motion over the differential motion as bellow,

$$\text{CDMR} \equiv \sqrt{\frac{\text{Common Motion}}{\text{Differential Motion}}} = \sqrt{\frac{P_{\text{comm}}(\omega)}{P_{\text{diff}}(\omega)}} \quad (1.2)$$

,where $P_{\text{comm}}, P_{\text{diff}}$ is the power spectrum densities (PSDs) of them. These are estimated by the autocorrelation function of these with the Wiener-Khinchin theorem.

Autocorrelation function C_{diff} is given by

$$C_{\text{diff}}(\tau) = \frac{1}{2} \left\langle \left[x_1(t) - x_2(t) \right] \left[x_1(t + \tau) - x_2(t + \tau) \right] \right\rangle \quad (1.3)$$

$$= \frac{1}{2} \left[C_{11}(\tau) - C_{12}(\tau) - C_{21}(\tau) + C_{22}(\tau) \right], \quad (1.4)$$

,where C_{ij} are the autocorrelation functions of each location and defined as $C_{ij} \equiv \langle x_i(t) x_j(t + \tau) \rangle$, ($i = 1, 2, j = 1, 2$). Therefore, the power spectrum density of differential motion $P_{\text{diff}}(\omega)$ can be computed as

$$P_{\text{diff}}(\omega) = \frac{1}{2} \left[P_1(\omega) + P_2(\omega) - P_{12}(\omega) - P_{12}^*(\omega) \right] \quad (1.5)$$

$$= \frac{1}{2} \left[P_1 + P_2 - \text{Re}[\text{coh}] \times 2\sqrt{P_1 P_2} \right] \quad (1.6)$$

where $P_1(\omega)$, $P_2(\omega)$ are the power spectrum densities of each locations, and $P_{12}(\omega)$ are the cross spectrum between two location. coh is the complex coherence between them defined below.

$$\text{coh} \equiv \frac{P_{12}}{\sqrt{P_1 P_2}} \quad (1.7)$$

Assuming that $P_1 = P_2 \equiv P$, one can compute the CDMR using Eq.(1.2) as

$$\text{CDMR} = \sqrt{\frac{1 + \text{Re}[\text{coh}]}{1 - \text{Re}[\text{coh}]}}. \quad (1.8)$$

Eq.(1.8) indicate that CDMR can be expressed by only the coherence between of two locations.

(aaaaa)

Incidentally, If the coherence is known and the PSDs of two location are same, one can estimate the PSDs of differential motion using that of one location according to Eq.(1.6) as

$$P_{\text{diff}} = P\sqrt{1 - \text{Re}[\text{coh}]}. \quad (1.9)$$

This expression is usefull to estimate a length fluctuation of the arm cavity even single point measurement because the coherence can be calculate using some models which is discussed following subsection.

Single Plane Wave Model

The CDMR when single plane wave propagates along the arm cavity is discussed. This model can be applied in the case the source of seismic motion is only one such as an earth quake. Assuming that the plane wave propagates with the azimuth angle θ along the direction of arm cavity, the wave length λ is $\lambda/\cos\theta$. In this situation, the coherence from x_1 to x_2 is denoted as

$$\text{coh} = e^{i\frac{L\cos\theta\omega}{c}} \quad (1.10)$$

Therefore, one can compute the CDMR as

$$\text{CDMR} = \sqrt{\frac{1 + \cos(\frac{L\omega}{c}\cos\theta)}{1 - \cos(\frac{L\omega}{c}\cos\theta)}}. \quad (1.11)$$

Uniform Plane Wave Model

The CDMR when the plane waves are distributed uniformly around the azimuth is discussed. This model can be applied in the case microseisms excite the ground. The coherence is equal to the integral over all direction.

$$\text{coh} = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{i\frac{\omega}{c}L\cos\theta} d\theta \quad (1.12)$$

where the coherence is normized azimuth angle. Therefore, the CDMR is given as

$$\text{CDMR} = \sqrt{\frac{1 + J_0(\frac{L\omega}{c})}{1 - J_0(\frac{L\omega}{c})}}. \quad (1.13)$$

1.4.3 Reduction Effect in the Arm Cavity

Figure 1.2: (Caution!! This plot shows the case of single plane wave.) CDMR in the case of the uniform plane wave model. (Upper) The amplitude spectrum densities of the differential and common motion in X arm cavity which is measured by seismometers near the each ITMX and ETMX chambers. (Lower) CDMR which is a ratio of the amplitudes of the common motion over differential motion, is shown in black line. Green Line is CDMR in the case the uniform plane wave model. Blue line is CDMR with no correlation between each mirrors.

Fig.(1.2) shows the CDMR in the X-arm with the uniform plane wave model. To compute the CDMR defined in Eq.(1.2), these ASDs of differential and common motion are calculated with the timeseries signals of seismometers using Eq.(1.1) before FFT.

1.4.4 Comparizon with surface detectors

When length of the arm is almost the same, CDMR depends only on the phase velocity on of the ground, according to models in Eq.(1.11), Eq.(1.13). The phase Velocity is ...

Phase Velocity Estimation

I'm tired. I'll write tomorrow.

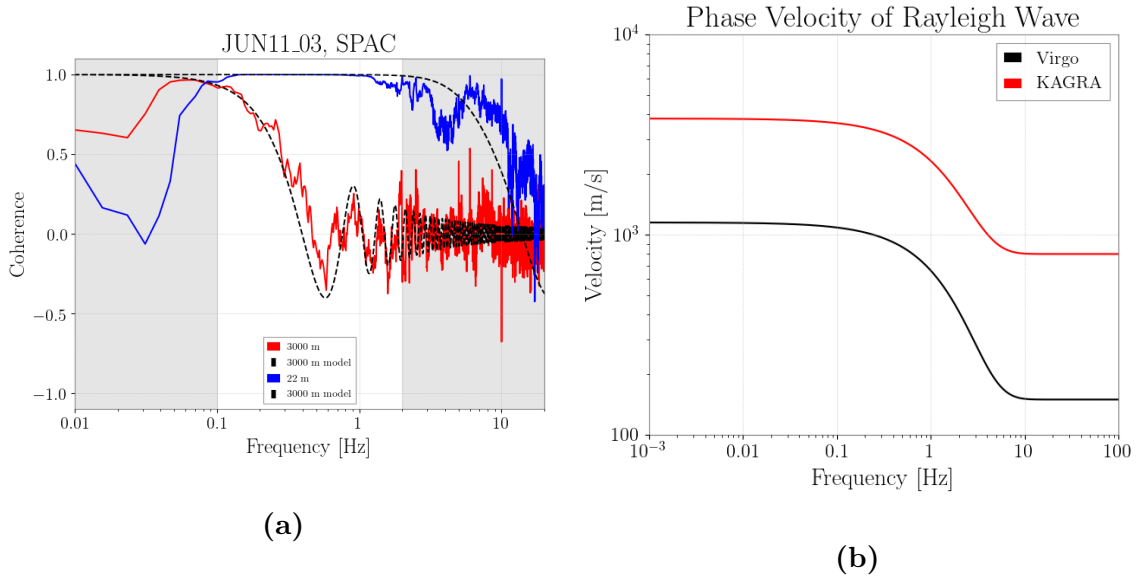

Figure 1.3: (a) The complex coherence between two locations. Red solid line is a complex coherence in 3000 m distance. Blue one is a coherence in 22 m distance. Black dashed line is given by Eq.(1.12) with assuming a profile of the phase velocity on Fig.(1.3b). (b) The phase velocity of the Rayleigh wave. Black solid line is sited from M.Beker's PhD thesis. Red one is taken by fitting the measured data on Fig.(1.3a)

Figure 1.4: Comparizon of the Reduction effect between KAGRA and Virgo. Eq.(1.9) with the phase velocity on the Fig.(1.3b)

1.5 Summary of the Chapter
